Modelling Methodologies

Types of data analysis

Descriptive

¿What did happen?

Diagnosis

¿Why does it happen?

Predictive

¿What will happen?

Prescriptive

¿What do I need to do?

Some questionable conclusions

Be careful with the
arithmetical mean in
Descriptive Analysis

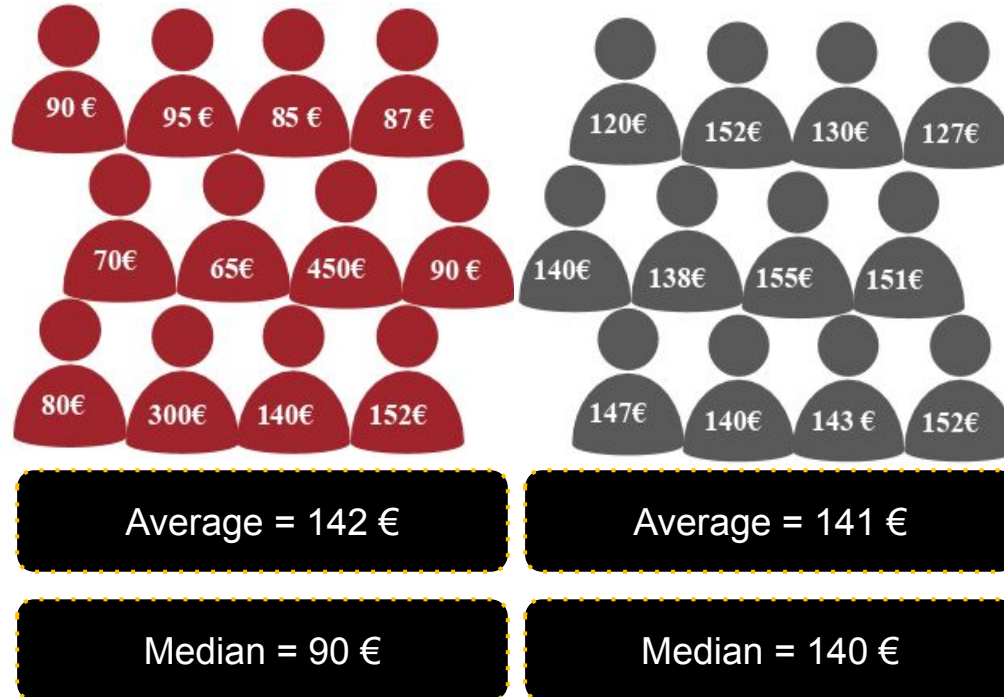

¿Which population is better?

¿Which population is better?

¿Which population is better?

The importance of the statistical distribution of a variable

customer A

Spending **A** = 1.000 €
Spending **B** = 1.000 €
Spending **C** = 1.000 €

customer B

customer C

Frequency **A** = 12
Frequency **B** = 12
Frequency **C** = 12

Distribution of three customers' spending along 12 months

Spending A = 1.000 €
Spending B = 1.000 €
Spending C = 1.000 €

Frequency A = 12
Frequency B = 12
Frequency C = 12

Be careful with
comparisons

Are trully comparable?

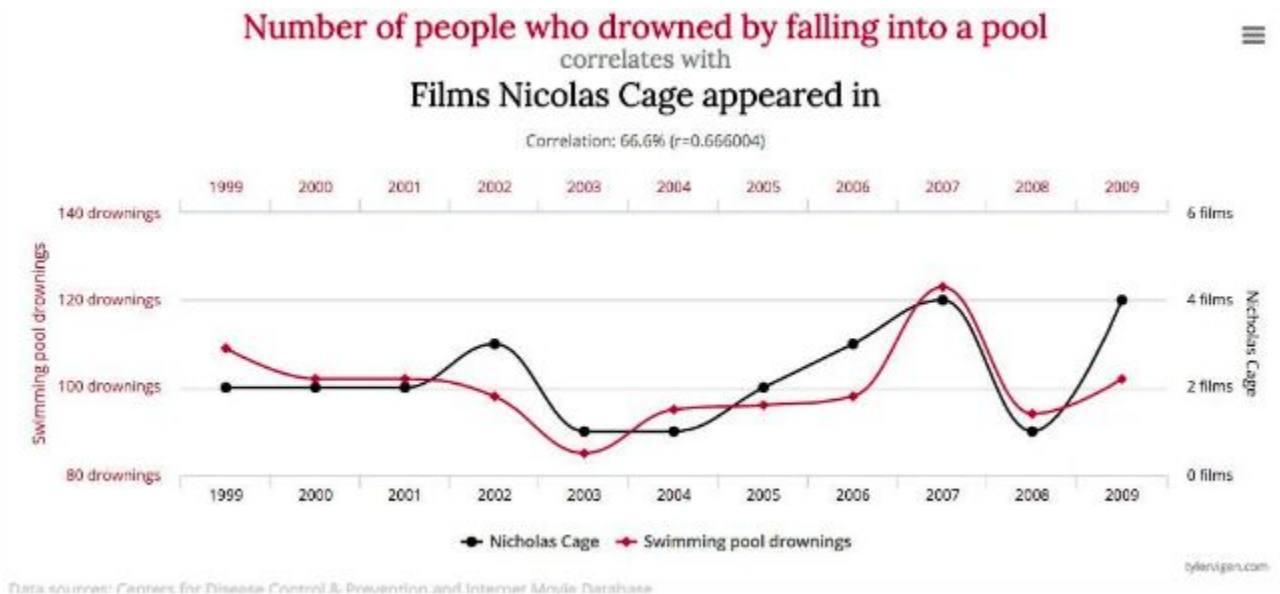

- Let's imagine that one of them are women and the other one are men.
- Let's imagine that one of them are customers and the other one are employees.

It is necessary the same starting point.
In another case, we will have the obvious, instead of learnings.

Relationship between
variables does not
imply causal relation

When Nicolas Cage acts, the number of people who drown by falling into a pool increase.

A mathematical model

A **mathematical model** is a description of a system using mathematical concepts and language. A model may help to explain a system and to study the effects of different components, and to make predictions about behaviour.

Example of a model:

Objective

How could I measure the maximum heart rate?

Example of a model:

Data that I
have

	Sexo	Edad	FCM
1	Mujer	37	185
2	Mujer	71	163
3	Hombre	25	210
4	Mujer	22	198
5	Hombre	48	179

each line
represents
a person

...

Example of a model:

Results

Modelling Methodologies

General types of learnings

Supervised learning

Here is the data set where the right answers [labels] are given for each example. Please, produce more right answers.

Unsupervised learning

Here is the unlabelled data. Please, find peculiarities, similarities or structures (e.g. clusters) in the data yourself.

Reinforcement learning

Learn to do something yourself purely by maximising your expected reward.

Modelling Methodologies

General
types of
learnings

Supervised learning

Here is the data set where the right answers [labels] are given for each example. Please, produce more right answers.

Regression

Predict a continuous valued output.

Classification

Predict a discrete valued output (eg. a label or a class).

Unsupervised learning

Here is the unlabelled data. Please, find peculiarities, similarities or structures (e.g. clusters) in the data yourself.

Clustering

Group similar examples into subsets called clusters.

Dimensionality reduction

Maybe you don't need all the data. What is the essence of the data?

Reinforcement learning

Learn to do something yourself purely by maximising your expected reward.

This can be a goal on its own but is often used as a pre-processing step for other ML tasks

General
types of
problems

Regression

Predict a number:
eg PRICE

Classification

Predict a label:
eg PURCHASE / NON-PURCHASE

Unsupervised Learning

Learning by comparison

Clustering

Finding elements alike:
eg CUSTOMER SEGMENTATION
according to their habits

Dimensionality Reduction

Explaining elements with less
attributes

Example: Predicting House Prices

Problem Statement We would like to predict the price of a house according to its characteristics.

Example: Predicting House Prices

Machine Learning requires explaining reality as a table of features.

010101001101010101001001101010101010010101100101

Id	LotArea	GrLivArea	GarageArea	PoolArea	SalePrice
1	8450	196.0	1710	548	208500
2	9600	0.0	1262	460	181500
3	11250	162.0	1786	608	223500
4	9550	0.0	1717	642	140000
5	14260	350.0	2198	836	250000

Example: Predicting House Prices

Features Description

each line
represents
a house

Id	LotArea	GrLivArea	GarageArea	PoolArea	SalePrice
1	845	196.0	171	54	208500
2	960	0.0	126	46	181500
3	1125	162.0	178	60	223500
4	955	0.0	171	64	140000
5	1426	350.0	219	83	250000

target

Example: Predicting House Prices

Machine Learning uses models to explain relationship between features.

In this case, we look for a function that explains the SalePrice:

$$\text{SalePrice} = f(\text{Features})$$

Example: Predicting House Prices

Linear Regression

A linear regression tries to find a linear function.

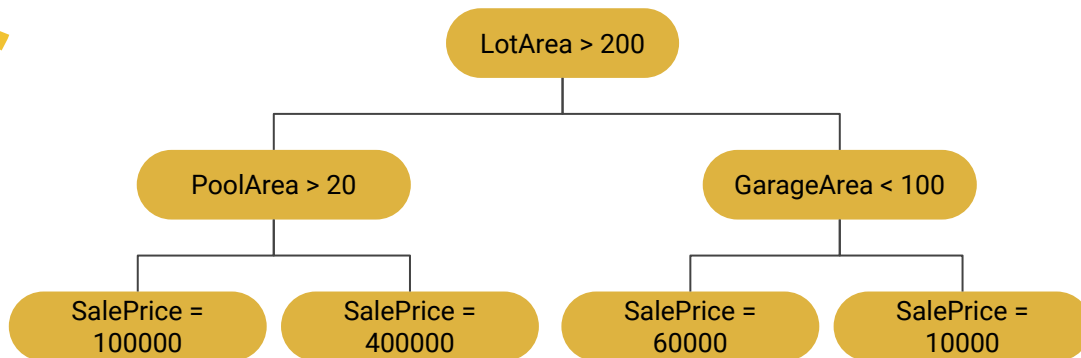

$$\text{SalePrice} = a * \text{LotArea} + b * \text{GrLivArea} + c * \text{GarageArea} + d * \text{PoolArea}$$

We need to find the best a,b,c,d to have the best relationship.

Example: Predicting House Prices

Decision Tree

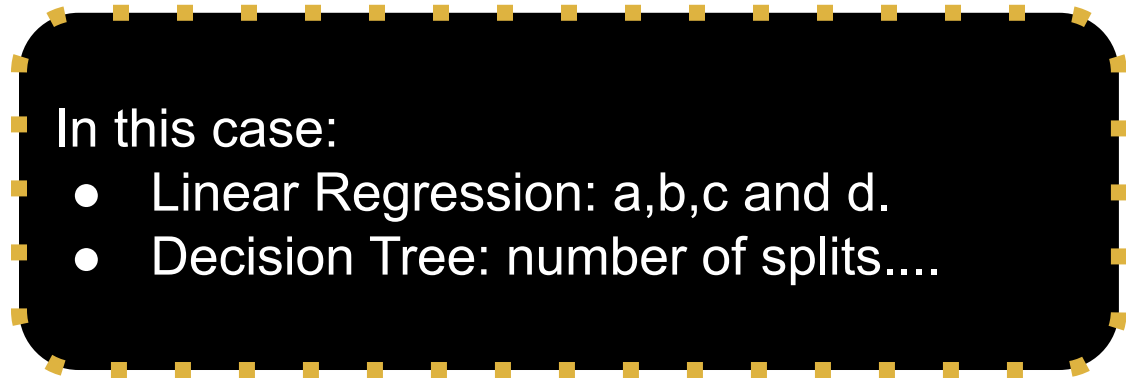

A decision tree tries to find a path to explain the target:

We need to find the best splits for our predictions.

Example: Predicting House Prices

The Data Scientist works to find the best parameters for the model.

- 
- In this case:
 - Linear Regression: a, b, c and d .
 - Decision Tree: number of splits....

How do you find the best parameters?

Example: Predicting House Prices

There are several metrics that can be chosen for this task. For example:

- Bias: Average of the errors
- MAE: Average of the absolute values of errors
- RMSE: Square root of Average of the square of errors

$$MBE = \frac{1}{N} \sum_{i=1}^N (x_{f,i} - x_{o,i})$$

$$MAE = \frac{1}{N} \sum_{i=1}^N |x_{f,i} - x_{o,i}|$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_{f,i} - x_{o,i})^2}$$

We chose the model parameters that provide the best METRIC.

In this case, let's use MAE:

$$\frac{|RealPrice1 - PredictedPrice1| + |RealPrice2 - PredictedPrice2| + \dots}{Number\ of\ houses}$$

Example: Predicting House Prices

Once we have the best parameters for a type of model, we can rank the models with the best metric they had

- 
- A black rectangular box with rounded corners and a dashed yellow border. It contains text about MAE values for different models.
- In this case: MAE:
 - Linear Regression: 15
 - Decision Tree: 10

And we ultimately choose the model with the best metric.

Example: Predicting chewing gum buyers

Problem Statement We would like to predict the customers who buy chewing gum.

Example: Predicting chewing gum buyers

Features Description

each line
represents
a customer

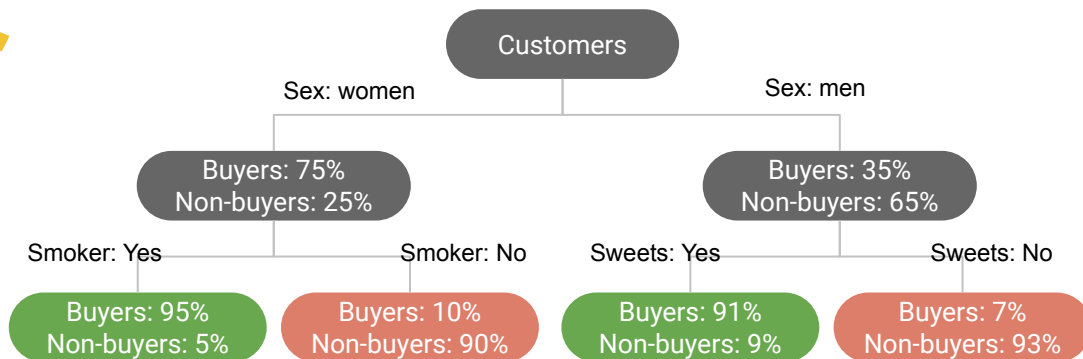

Id	Sex	Age	Smoker	Sweets	GumBuyer
1	Woman	19	Yes	No	Yes
2	Woman	45	No	No	No
3	Man	53	Yes	No	Yes
4	Woman	21	No	Yes	Yes
5	Man	35	No	Yes	No

target

Example: Predicting chewing gum buyers

Decision Tree

A decision tree tries to find a path to explain the target:

We need to find the best parameters for the model: number of splits, minimum number of member per group...

Classification metrics: Confusion matrix

		Predicted Class	
		Positive	Negative
Actual Class	Positive	True Positive (TP)	False Negative (FN) Type II Error
	Negative	False Positive (FP) Type I Error	True Negative (TN)

Classification metrics: Confusion matrix

		Predicted Class		
		Positive	Negative	
Actual Class	Positive	True Positive (TP)	False Negative (FN) Type II Error	Sensitivity $\frac{TP}{(TP + FN)}$
	Negative	False Positive (FP) Type I Error	True Negative (TN)	Specificity $\frac{TN}{(TN + FP)}$
		Precision $\frac{TP}{(TP + FP)}$	Negative Predictive Value $\frac{TN}{(TN + FN)}$	Accuracy $\frac{TP + TN}{(TP + TN + FP + FN)}$

Example: Salmon and sea bass

Problem Statement

I would like to discern
between salmon and
sea bass.

Example: Salmon and sea bass

A fish-packing plant wants to automate the process of sorting incoming fish according to species.

As a pilot project, it is decided to try to separate sea bass from salmon using ML.

We know they are different but we don't know what features make them different.

Let's go.

Example: Salmon and sea bass

Some features to explore:

- Length
- Scale density
- Width
- Position of the mouth
- ...

Example: Salmon and sea bass

Start by checking length of each fish:

They have different distributions. Notice that salmon tends to be shorter than sea bass.

Example: Salmon and sea bass

Find the best length L threshold:

fish length $< L$

classify as a salmon

fish length $> L$

classify as a sea bass

After searching through all possible thresholds L , the best $L = 9$, and still 30% of fish is misclassified.

We cannot reliably separate sea bass from salmon by length alone!

Example: Salmon and sea bass

I have to continue
looking for...

Example: Salmon and sea bass

Next feature I can consider:
Scale density

The two classes are much better separated!

Example: Salmon and sea bass

Lets to combine the two features:

We have reduced the error rate below 5%.

Should we be satisfied with this result?

Example: Salmon and sea bass

And... what could we
do now?

Example: Salmon and sea bass

Options we have:

- Consider additional features:
 - Which ones?
 - Some features may be redundant (e.g., if eye color perfectly correlates with width, then we gain no information by adding eye color as feature.)
 - It may be costly to attain more features
 - Too many features may hurt the performance
- Use a more complex model

Example: Salmon and sea bass

Options we have:

- Consider additional features:
 - Which ones?
 - Some features may be redundant (e.g., if eye color perfectly correlates with width, then we gain no information by adding eye color as feature.)
 - It may be costly to attain more features
 - Too many features may hurt the performance
- Use a more complex model

Example: Salmon and sea bass

With a more complex model all data are perfectly separated :

Should we be satisfied now??

Example: Salmon and sea bass

We must consider:

Which decisions will the classifier take on novel patterns, i.e. fishes not yet seen?

Will the classifier suggest the correct actions?

This is the issue of
GENERALIZATION

Measurement of the model

We take the available features table and we split in 2 sets:

1 set to calculate parameters: **Training Set**

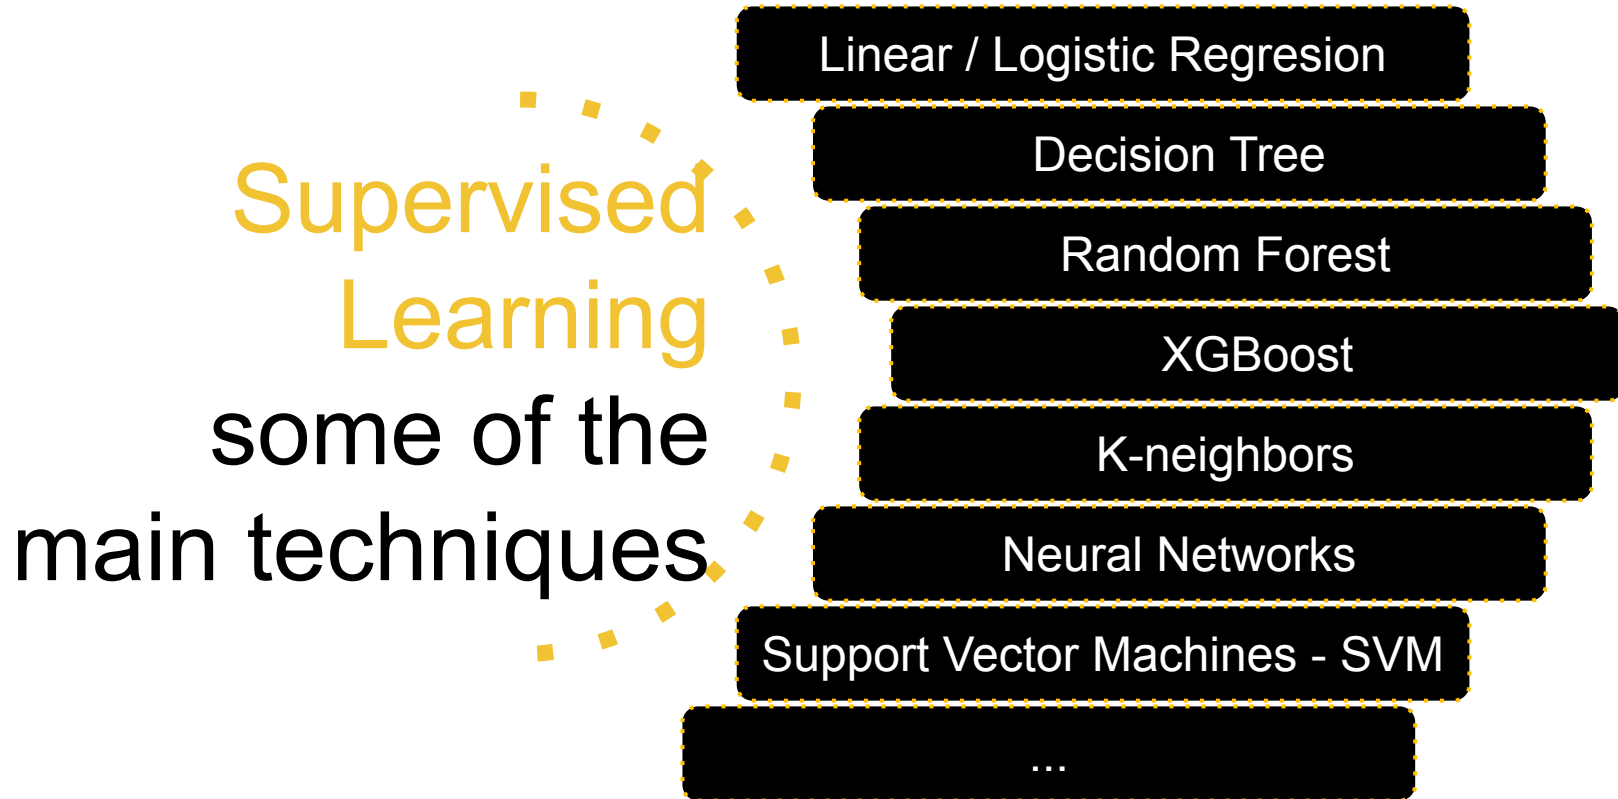

1 set to calculate metrics: **Test Set**

	Length	DensityScale	Width	...
1	10000	37	1385	...
2	12350	71	1613	...
3	9871	25	2100	...
4	15431	22	1985	...
5	5200	48	1791	...
...
...
...
...
...
...

Summary: ML is about features, models and metrics

- ML requires explaining reality as a table of **features**
- We then use **models** to explain relationships between features for the given ML task
- Each model is evaluated according to a **metric**

And many others... The list is growing thanks to the active research.

Hands on Exercises

Let's try to do next two exercises:

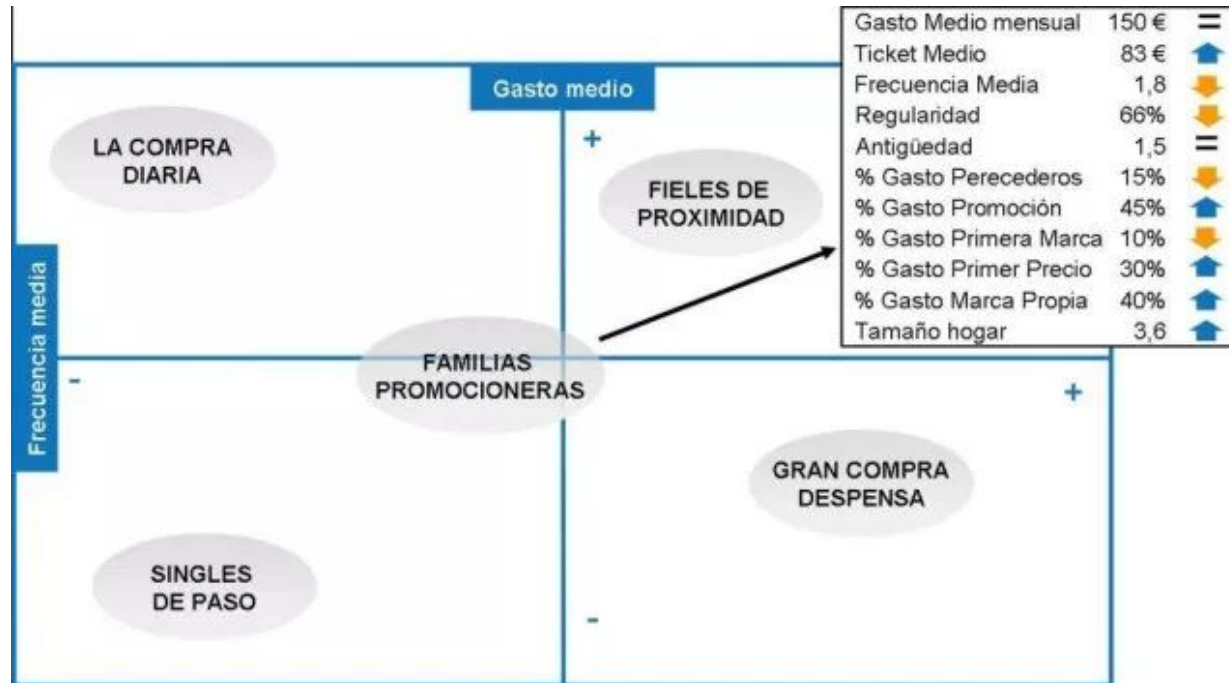

1. Exercise_1: Compare models' predictions and decide which is the best one with different metrics.
2. Exercise_2: Build the confusion matrix and calculate main metrics about it.
 - a. Which is the best model in general?
 - b. Which identify better the 1 class?

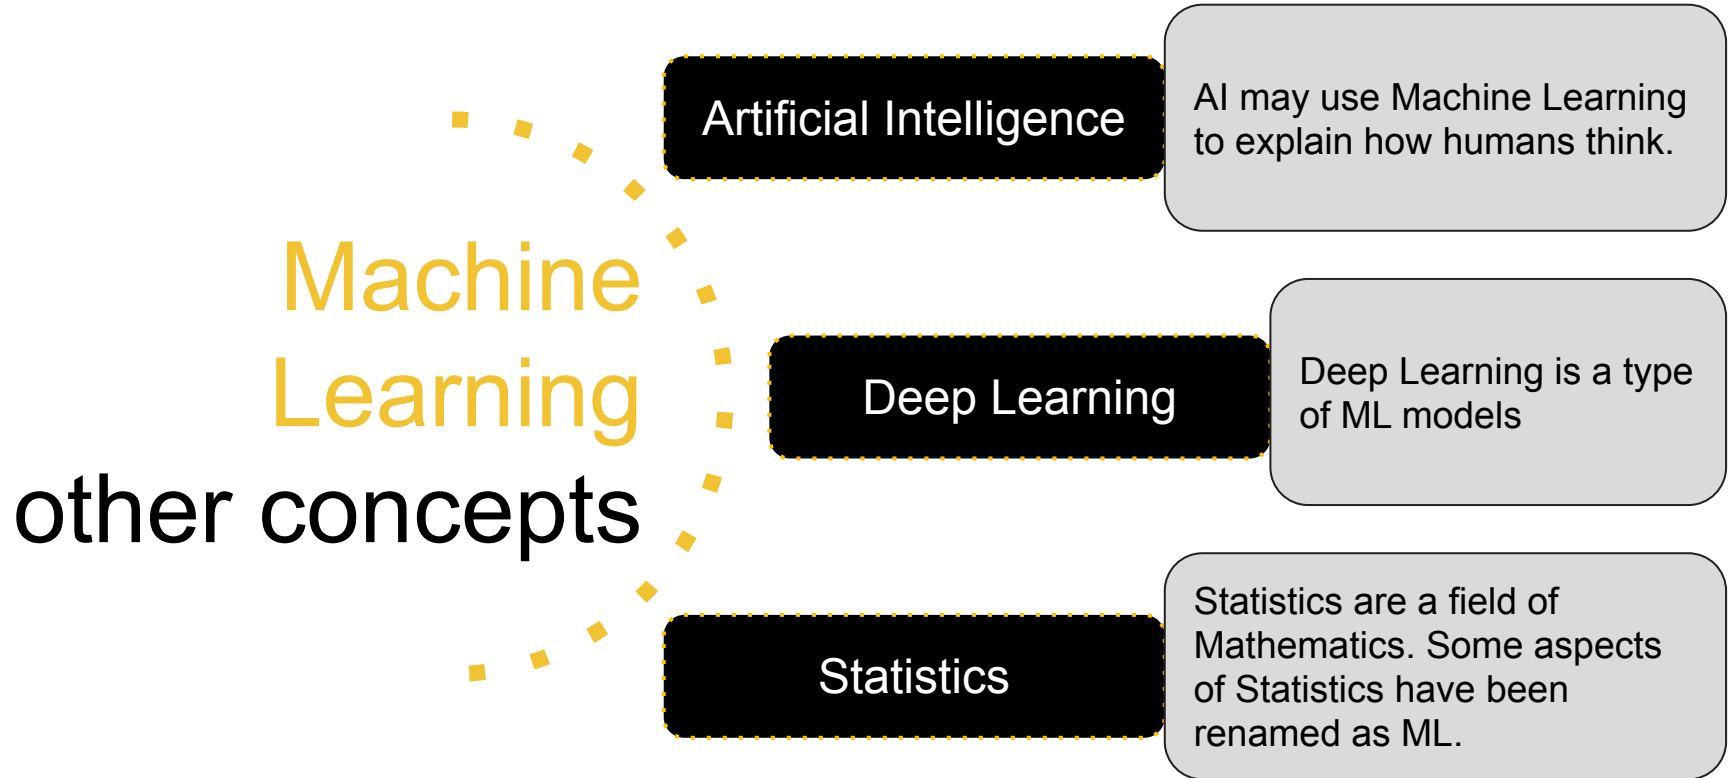

Unsupervised
Learning
the main type of
problems.

Clustering

Example of clustering: department store

ML Canvas

Translating a Business Problem to ML

Any Business Problem can be analyzed through the following axes:

1. Business Value and Measure of Success.
2. Data Sources
3. ML task + metric
4. Features Extraction + Model Creation
5. Industrialization and Maintenance
